IC50 & Target[1][2]	HIV-1																							
体外研究(In Vitro)	<p>Darunavir is a broad-spectrum potent inhibitor active against HIV-1 clinical isolates with minimal cytotoxicity. Darunavir forms hydrogen bonds with the conserved main-chain atoms of Asp29 and Asp30 of the protease. These interactions are proposed to be critical for the potency of this compound against HIV isolates that are resistant to multiple protease inhibitors. In an 体外研究 study in MT-2 cells, the potency of darunavir is greater than that of saquinavir, amprenavir, nelfinavir, indinavir, lopinavir and ritonavir. Darunavir is primarily metabolized by the hepatic cytochrome P450 (CYP) enzymes, primarily CYP3A. The 'boosting' dose of ritonavir acts as an inhibitor of CYP3A, thereby increasing darunavir bioavailability.</p> <p>Medlife has not independently confirmed the accuracy of these methods. They are for reference only.</p>																							
体内研究(In Vivo)	<p>Darunavir is effective against wild-type and PI-resistant HIV, and has an oral bioavailability of 37%. It needs to be combined with ritonavir, which increases the bioavailability to 82%.</p> <p>Medlife has not independently confirmed the accuracy of these methods. They are for reference only.</p>
